Salvador Dali: *The swallow’s tail*
Introduction

Pairs of \emph{relatively prime} positive integers

\[(n, q)\]

with

\[q < n\]

classify simple \textit{geometric, algebro-geometric, combinatoric, group theoretic} and \textit{invariant theoretic} objects. These are in several ways connected with each other by concrete constructions. Here, the \textit{continued fraction expansions} of the rational numbers

\[\frac{n}{q} \text{ resp. } \frac{n}{n-q}\]

play an essential role. Replacing \(q\) by \(n - q\) reflects various types of \textit{duality}. 

Oswald Riemenschneider (Hamburg)

Toric duality between \(A_{n,q}\) and \(A_{n,n-q}\)

Lecture Kagoshima Univ. 3 / 58
Plan of lecture

1. Continued fraction expansions
2. Generation of certain semi-groups
3. Toric varieties of type $A_{n,q}$
4. Cyclic quotient surface singularities
5. Deformations
6. Duality for the Artin deformation
1. Continued fraction expansions
A variant of the Euclidean Algorithm is given by *Division “with smallest excess”*, i.e.

\[
n = b_1 q - q_1, \quad 0 < q_1 < q,
\]

\[
q = b_2 q_1 - q_2, \quad 0 \leq q_2 < q_1,
\]

\[
\ldots
\]

\[
q_{r-2} = b_r q_{r-1} - q_r, \quad 0 = q_r.
\]

which leads to a semi-regular continued fraction expansion:

\[
n/q = b_1 - \frac{1}{b_2} - \cdots - \frac{1}{b_r}, \quad b_\rho \geq 2.
\]
Example: 47/11

\[
\frac{47}{11} = 5 - \frac{1}{2} - \frac{1}{2} - \frac{1}{3} - \frac{1}{2}
\]

\[
5 - \frac{1}{\sqrt{2}} = \frac{9}{2}
\]
Continued fraction expansions

Example: $\frac{47}{11}$

$\frac{47}{11}$ once more

$5 - \frac{1}{2} - \frac{1}{2} - \frac{1}{3} - \frac{1}{2} = \frac{13}{3}$

$5 - \frac{1}{2} = \frac{9}{2}$

$47/11 = 5 - \frac{1}{2} - \frac{1}{2} - \frac{1}{3} - \frac{1}{2}$
Continued fraction expansions

Example: 47/11

47/11 once more

\[ \frac{47}{11} = 5 - \frac{1}{2} - \frac{1}{2} - \frac{1}{3} - \frac{1}{2} \]

\[ 5 - 1 \frac{2}{2} = 9/2 \]

\[ 5 - 1 \frac{2}{2} - 1 \frac{2}{2} = 13/3 \]

\[ 5 - 1 \frac{2}{2} - 1 \frac{2}{2} - 1 \frac{3}{2} = 30/7 \]
2. Generation of certain semi - groups
Generation of certain semi-groups in $\mathbb{Z} \oplus \mathbb{Z}$

\[ 7/3 = 3 - \sqrt{2} - \sqrt{2} \]

- $3$
- $5/2$
- $7/3$
Generation of certain semi-groups

Oswald Riemenschneider (Hamburg)
Generation of certain semi-groups

Example

Oswald Riemenschneider (Hamburg)

Toric duality between $A_{n,q}$ and $A_{n,n-q}$

Lecture Kagoshima Univ.
The generating lattice points \( Q_\rho, \rho = 1, \ldots, r \), whose coordinates are exactly the nominator and denominator of the approximating fractions of \( n/q \), are most simply obtained by the inductive definition

\[
Q_{-1} := \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \quad Q_0 := \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad Q_\rho := b_\rho Q_{\rho-1} - Q_{\rho-2}.
\]

In our example we have the sequence 3, 2, 2 and - indeed - the generators

\[
Q_{-1} := \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \quad Q_0 := \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad Q_1 := \begin{pmatrix} 1 \\ 3 \end{pmatrix}, \quad Q_2 := \begin{pmatrix} 2 \\ 5 \end{pmatrix}, \quad Q_3 := \begin{pmatrix} 3 \\ 7 \end{pmatrix}.
\]

Hence, it is more natural to regard the larger cone

\[
\sigma := \{ (x, y) \in \mathbb{R}^2 : y \geq 0, \ nx \leq qy \}
\]

and the preceding sequence of generators for the semi-group \( \sigma \cap (\mathbb{Z} \oplus \mathbb{Z}) \).
Generation of certain semi-groups and continued fractions

Lecture Kagoshima Univ.
Generation of certain semi-groups

Lattice point transformations

Toric duality between $A_{n,q}$ and $A_{n,n-q}$
Duality

We are, however, mainly interested in the cones

$$\sigma_{n,q} := \{ (x, y) \in \mathbb{R}^2 : 0 \leq qy \leq nx \}$$

whose dual $\sigma_{n,q}^\vee$ of linear forms which are non negative on $\sigma_{n,q}$ is obviously given (after identifying $\mathbb{R}^2$ with its dual space):

$$\sigma_{n,q}^\vee := \{ (x, y) \in \mathbb{R}^2 : ny \geq -qx, x \geq 0 \}.$$

Corollary

$$\sigma_{n,q}^\vee \cong \sigma_{n,q}^c,$$

where the superscript “c” denotes the complement in the upper half plane.
Corollary

The semi-group

\[ \sigma_{n,q} \cap (\mathbb{Z} \oplus \mathbb{Z}) \]

is minimally generated by the lattice points \( P_\mu, \mu = 0, \ldots, m + 1 \), where

\[ P_0 := \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad P_1 := \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \quad P_{\mu+1} := a_\mu P_\mu - P_{\mu-1} \]

and

\[ n/(n - q) = a_1 - 1\overline{a_2} - \cdots - 1\overline{a_m}. \]
3. Toric varieties of type $A_{n,q}$
Affine toric Varieties

Affine toric varieties of dimension $N$ are combinatorically determined by so called strongly convex rational polyhedral cones $\sigma$ in $\mathbb{R}^N$. In case $N = 2$, these are simply (closed semi-) cones that are bordered by two half-lines with rational slope and do not contain any line through the origin. In other words: There exist lattice points $\gamma_1$ and $\gamma_2$ in $\mathbb{Z} \oplus \mathbb{Z} \subset \mathbb{R}^2$ such that

$$\sigma = \mathbb{R}_{\geq 0} \gamma_1 + \mathbb{R}_{\geq 0} \gamma_2 \quad \text{and} \quad \sigma \cap (-\sigma) = \{0\}.$$ 

If identifying the dual space of $\mathbb{R}^N$ with $\mathbb{R}^N$ itself, then the dual cone $\sigma^\vee$ of linear forms which are non negative on $\sigma$ is of the same type, and the algebra

$$\mathbb{C} [\sigma^\vee] := \mathbb{C} [s_1^{i_1} \cdots s_N^{i_N} : (i_1, \ldots, i_N) \in \sigma^\vee \cap \mathbb{Z}^N]$$

will be finitely generated, hence its spectrum is an affine algebraic variety, called the affine toric variety associated to the cone $\sigma$. 
Two smooth examples

Toric duality between $A_{n,q}$ and $A_{n,n-q}$
Affine toric varieties of type $A_{n,q}$

Given the pair $(n, q)$, we call the affine toric variety associated to the cone $\sigma_{n,q}^\vee = \sigma_n^c$ the toric variety of type $A_{n,q}$ and denote it by the symbols $X_{n,q}$ or $X(a_1, \ldots, a_m)$.

**Example**

For $q := n - 1$, one has $n/(n - q) = n$. Therefore, the ring of regular/holomorphic functions of the affine toric variety associated to the cone $\sigma_{n,n-1}^\vee$ will be generated by the monomials

$$x_0 = s, \quad x_1 = st, \quad x_2 = s^{n-1} t^n$$

with the generating relation

$$x_0 x_2 = x_1^n$$

such that singularities of type $A_{n,n-1}$ are the simple singularities of type $A_{n-1}$.
Octdong

Dingdong
The cone over the rational normal curve of degree $n$

Generating monomials: $x_0 := s$, $x_1 = st$, $x_2 := st^2, \ldots, x_n = st^n$.

Equations: Vanishing of all $2 \times 2$ - minors of the matrix

$$
\begin{pmatrix}
x_0 & x_1 & \cdots & x_{n-2} & x_{n-1} \\
x_1 & x_2 & \cdots & x_{n-1} & x_n
\end{pmatrix}.
$$
The resolution of the cone singularities

The previous equations can be viewed as the projective equations of a curve in projective space $\mathbb{P}_n$; it is isomorphic to the projective line $\mathbb{P}_1$ under the Veronese embedding with respect to the line bundle $\mathcal{O}_{\mathbb{P}_1}(n)$. The (minimal) resolution of the cone singularity is well known to being isomorphic to the total space of the dual bundle $\mathcal{O}_{\mathbb{P}_1}(-n)$.

This can also be understood via toric geometry: One has to decompose the rational cone $\sigma$ in such a manner into a fan such that the “subcones” are generated by $\mathbb{Z}$-bases of $\mathbb{Z} \oplus \mathbb{Z}$ and the corresponding affine varieties are suitably patched together.

In our example this leads to the following picture and patching rule:

$$t = v^{-1}, \quad s = w v^n$$
Schematic picture of the resolution
In the general case \((n, q)\) one has to regard the following cone and its fan decomposition:

The resolution hence arises by gluing \(r\) holomorphic line bundles.
Toric varieties of type $A_{n,q}$

The general case

Oswald Riemenschneider (Hamburg)

Toric duality between $A_{n,q}$ and $A_{n,n-q}$

Lecture Kagoshima Univ. 26 / 58
Toric Varieties

General *toric varieties* are constructed by gluing affine toric varieties; the underlying combinatorics is encoded again in fans.

**Example:** The fan for $\bar{X}_{n,q}$.
Resolution of $\overline{X}_{n,q}$

$$\frac{7}{3} = 3 - \frac{1}{2} - \frac{1}{2}, \quad \frac{7}{4} = 2 - \frac{1}{4}$$
This is necessarily a *modification* of the trivial line bundle $\mathbb{P}_1 \times \mathbb{C}$. More precisely, it is

$$
\begin{array}{cccccc}
-2 & -4 & -1 & -2 & -2 & -3 \\
\end{array}
$$

In fact, one can blow this configuration down symbolically as follows:

$$
\begin{array}{ccccccc}
2 & 4 & 1 & 2 & 2 & 3 \\
2 & 3 & 1 & 2 & 3 \\
2 & 2 & 1 & 3 \\
2 & 1 & 2 \\
1 & 1 \\
0 \\
\end{array}
$$
4. Cyclic quotient surface singularities
Holomorphic operations of cyclic groups

Local quotients of $\mathbb{C}^N$ by a finite group $\Gamma$ of local holomorphic automorphisms are - per definitionem - the spectrum of the invariant ring $\mathbb{C}\{u_1, \ldots, u_N\}^\Gamma$.

Local quotients of $\mathbb{C}^2$ by a finite cyclic group of holomorphic automorphisms are isomorphic to the quotients

$$\mathbb{C}^2/\Gamma_{n,q},$$

where the group $\Gamma_{n,q}$ is generated by the diagonal matrix

$$\text{diag}(\zeta_n, \zeta_n^q)$$

with an $n$-th primitive root of unity $\zeta_n$ and $q$ with $1 \leq q < n$ relatively prime to $n$.

One has $\mathbb{C}^2/\Gamma_{n,q} \cong \mathbb{C}^2/\Gamma_{n',q'}$ if and only if $n = n'$ and $q = q'$ or $n = n'$ and $qq' \equiv 1 \pmod{n}$.
The invariant ring

The invariant ring \( \mathbb{C}[u, v]^\Gamma_{n,q} \) consists obviously of all polynomials in the monomials \( u^i v^j \) with \( i + qj = kn \). The corresponding lattice can (after suitable lattice point transformation and normalization) be transferred to the lattice of the singularity \( A_{n,q} \):

\[
(n,q) = (7,4) \quad \text{n/n - q = 7/3 = 3 - 1\sqrt{2} - 1\sqrt{2}}
\]

Corollary

\[
\mathbb{C}^2 / \Gamma_{n,q} \cong X_{n,q}, \quad (\mathbb{P}1 \times \mathbb{C}) / \Gamma_{n,q} \cong \overline{X_{n,q}}.
\]
Putting with \( n/(n - q) = a_1 - \frac{1}{a_2} - \cdots - \frac{1}{a_m} \):

\[
i_0 = n, \ i_1 = n - q, \ i_{\mu+1} = a_\mu \ i_\mu - i_{\mu-1},
\]
\[
j_0 = 0, \ j_1 = 1, \ j_{\mu+1} = a_\mu \ j_\mu - j_{\mu-1},
\]

this implies:

**Theorem**

The monomials

\[
\chi_\mu = u^{i_\mu} \ v^{j_\mu}, \ \mu = 0, \ldots, m + 1
\]

form a minimal generating system of the invariant ring referring to the group \( \Gamma_{n,q} \).

In particular, the singularity \( X_{n,q} \) possesses the embedding - dimension

\[
e = m + 2.
\]
Multiplicity and equations

As every rational singularity of embedding dimension \( e \) the singularity \( X(a_1, \ldots, a_m) \) has the multiplicity \( e - 1 = m + 1 \) and a minimal generating system of equations of cardinality

\[
\binom{e - 1}{2} = \binom{m + 1}{2}.
\]

They can be written in quasi-determinantal form:

\[
\begin{pmatrix}
x_0 & x_1 & x_2 & \cdots & x_{m-1} & x_m \\
x_1^{a_1-2} & x_2^{a_2-2} & \cdots & \cdots & x_m^{a_m-2} \\
x_1 & x_2 & x_3 & \cdots & x_m & x_{m+1}
\end{pmatrix}
\]
5. Deformations
**Versal Deformations**

Versal Deformations exist e. g. for

1. isolated singularities
2. resolutions of isolated singularities
3. compact complex spaces
4. holomorphic vector bundles on fixed base spaces
Deformations

Versal Deformations

\[ \mathcal{X}_{\text{vers}} \]

\[ \downarrow \]

\[ S_{\text{vers}} \]
Deformations

Versal Deformations

\[
\begin{array}{c}
\mathcal{X} \\
\downarrow \\
S \\
\end{array}
\quad
\begin{array}{c}
\mathcal{X}_{\text{vers}} \\
\downarrow \\
S_{\text{vers}} \\
\end{array}
\]

Oswald Riemenschneider (Hamburg)

Versal Deformations

\[ x \rightarrow x_{\text{vers}} \]

\[ S \rightarrow S_{\text{vers}} \]

Oswald Riemenschneider (Hamburg)

Toric duality between $A_{n,q}$ and $A_{n,n-q}$

Lecture Kagoshima Univ. 37 / 58
The Versal Deformation of the Resolution

The versal deformation \( \tilde{X} \rightarrow T_{\text{vers}} \) of the resolution \( \tilde{X}_{n,q} \) can explicitly be written down where \( T_{\text{vers}} \) is a smooth base space of dimension

\[
\dim T_{\text{vers}} = \sum_{\rho=1}^{r} (b_{\rho} - 1).
\]

This deformation can fiberwise be blown down by a general theorem of Wahl and R. to a deformation of the given singularity (the “Artin deformation”), and due to a theorem of M. Artin and Lipman there exists a smooth component \( S_{\text{art}} \) of the versal base space \( S_{\text{vers}} \) (the “Artin component”) such that the existing mapping

\[
T_{\text{vers}} \rightarrow S_{\text{vers}}
\]

factorizes over \( S_{\text{art}} \); more precisely \( S_{\text{art}} = T_{\text{vers}}/W \).
The Artin component

In the case of a cyclic quotient singularity one can easily determine the total deformation over the Artin component as the “generic perturbations” of the quasi-determinantal formats of the given singularity $X(a_1, \ldots, a_m)$ over a smooth base space of dimension

$$
\sum_{\mu=1}^{m} (a_\mu - 1) :
$$

$$
\begin{pmatrix}
x_0 & x_1 + t_1 & x_2 + t_2 & \cdots & x_{m-1} + t_{m-1} & x_m + t_m \\
X_1^{(a_1-2)} & X_2^{(a_2-2)} & \cdots & \cdots & X_m^{(a_m-2)} \\
x_1 & x_2 & x_3 & \cdots & x_m & x_{m+1}
\end{pmatrix}
$$

with

$$
X_\mu^{(a_\mu-2)} := x_\mu^{a_\mu-2} + s_\mu^{(1)} x_\mu^{a_\mu-3} + \cdots s_\mu^{(a_\mu-2)} .
$$
The Artin deformation space over $T_{\text{vers}}$ can be obtained by linear factorization of the polynomials $X_\mu^{(a_\mu - 2)}$. The Weyl group $W$ is hence nothing else but the product of symmetric groups

$$W = \prod_{\mu=1}^{m} \mathfrak{S}_{a_\mu - 2}.$$ 

**Corollary**

$$\sum_{\mu=1}^{m} (a_\mu - 1) = \sum_{\rho=1}^{r} (b_\rho - 1).$$

**Remark**

*The last identity can also be derived directly from the continued fraction expansions.*
The dot - diagram

In case (47, 11) look at the following diagram:

```
  5  •  •  •  •  •

  2  •

  2  •

  3  •  •

  2  •

  2  2  2  5  3
```

From a similar diagram one can always read off the continued fraction expansion of $n/n - q$ from that of $n/q$ without knowing $n$ and $q$. 
Further components

From general reasons one can conclude that the deformations over $S_{\text{art}}$ are already versal for the small embedding dimensions 3 and 4. In case $e \geq 5$, i.e. $m \geq 3$, one knows, however, that

$$\dim T^1 = \sum_{\mu=1}^{m} a_{\mu} - 2 = \sum_{\mu=1}^{m} (a_{\mu} - 1) + (m - 2)$$

$$> \sum_{\mu=1}^{m} (a_{\mu} - 1).$$

Consequently, there must more components of the base space of the versal deformation exist, non-embedded ones (in which case these components of the base space must be smooth) or even embedded ones.
Example

- For $e = 5$ there exist always 2 "smooth" components and no embedded ones.
- For $e = 6$ there exist between one and five smooth components and embedded components, if the maximal number 5 is not attained.

Questions:

- How many such components exist for a given singularity $X_{n,q} = X(a_1, \ldots, a_m)$?
- And how can one describe them?
The monodromy coverings

For the determination of the possible singularities in neighboring fibers in general deformations one needs only this information for the deformation over the reduction of $S_{\text{vers}}$:

$$(\mathcal{X}_{\text{vers}})_{\text{red}} \longrightarrow (S_{\text{vers}})_{\text{red}}$$

which, by abuse of notation, we abbreviate by

$$\mathcal{X}_{\text{red}} \longrightarrow S_{\text{red}}.$$ 

It is well known (Christoffersen) that $S_{\text{red}}$ has only smooth components $S_j$, and for each $S_j$ there is a finite covering $T_j \rightarrow S_j$ such that the total space $\mathcal{Y}_j$ of the induced deformation over $T_j$ is equipped with a toroidal structure.
The monodromy coverings and the Artin component

The families $\mathcal{Y}_j \to T_j$ have no monodromy, in particular very special fiber singularities.

In particular, there is exactly one component $S_0$ of $S$ such that the family $\mathcal{Y}_0 \to T_0$ can be resolved simultaneously (without base change): the Artin component.

Remark

One part of Martin Hamm’s Hamburg dissertation (2008) is concerned with toroidal descriptions of the monodromy coverings $\mathcal{Y}_j \to T_j$ and even of the grand monodromy covering $\mathcal{Y} \to T$. 
6. Duality for the Artin deformation
Duality for the Artin deformation

Theorem (M. Hamm)

Let $X$ be the singularity $X_{n,q}$, and $X'$ the singularity $X_{n,n-q}$. Then their total Artin deformation spaces are dual to each other as affine toric varieties.

In other words: If the Artin deformation space of $X$ will be described by the pair $(\mathbb{L}, \Sigma)$, then the Artin deformation space of $X'$ will be described by $(\mathbb{L}^*, \Sigma^\vee)$.

More precisely: There is a simultaneous way how to describe the toric generators for the algebra defining this total space in case $X_{n,q}$ with the help of the continued fraction expansion for $n/(n-q)$, i.e. the “$a$ - series”, and how to find the inequalities of the underlying rational convex cone (up to isomorphism) by the expansion for $n/q$, i.e. the “$b$ - series”.
The case \( A_1 \)

The generators in case \( A_1 \) are given by the vectors

\[
e_0, e_0 + e_1, e_0 + 2e_1 \in \mathbb{Z}^2.
\]

(In the following, we always denote by \( e_0, \ldots, e_n \) the standard basis of \( \mathbb{R}^{n+1} \)). The four vectors

\[
x_0 = e_0, \ x_1 = e_0 + e_1, \ x'_1 = e_0 + e_2, \ x_2 = e_0 + e_1 + e_2 \in \mathbb{Z}^3
\]

project down to these three vectors under the projection \( e_2 \mapsto e_1 \). They satisfy the unique generating relation

\[
x_0 + x_2 = x_1 + x'_1.
\]

Therefore, this defines the toric generators for the Artin deformation in question, the projection corresponding to the embedding of the singularity as a fiber in this space.
It is easy to see that the generated cone will be described exactly by four inequalities leading to the dual cone on the right hand side. But this one is obviously the cone of the Artin deformation again if one starts a priori with $\sigma^c$ instead of $\sigma$. 

\[ y_1 - x - y_2 \]
These two cones are also complements of each other in some sense as one can better imagine when taking slides only:
The case $A_2$

A manifestation of the Artin deformation for $A_2$ in $\mathbb{R}^4$ is a generalization of the above mentioned cone which, after isomorphism, can also be realized by the following picture.
For general $n$, the cone giving the Artin deformation of $A_n$ should again be chosen with respect to the complementary cone in $\mathbb{R}^2$. Then, it is easy to determine the dual one:

$$0 \leq y_1 \leq x, \quad 0 \leq y_n \leq y_{n-1} \leq \cdots \leq y_2 \leq x.$$ 

**Case $A_2$:**
Example (4,2,3)

After an obvious lattice transformation, the generators for the Artin deformation can be written in the following “format”:

\[
\begin{pmatrix}
e_1 & e_4 & e_5 & e_7 \\
e_2 & e_3 & & e_6 \\
e_0 & & \times & \times & \times
\end{pmatrix}.
\]

The crosses have to be filled in in the “obvious correct” way. In this case, they have to be successively from left to right:

\[
f_1 = e_0 - e_1 + e_2 + e_3 + e_4,
\]
\[
f_2 = e_0 - e_1 + e_2 + e_3 + e_5,
\]
\[
f_3 = e_0 - e_1 + e_2 + e_3 + e_6 + e_7.
\]
Example (2,2,4,2)

One can easily compute generators for the dual cone according to this format:

\[ e_0, e_2, \ldots, e_7, e_0 + e_1, e_1 + e_2, e_1 + e_3, \]
\[ e_1 + e_4 + e_5 + e_6, e_1 + e_4 + e_5 + e_7. \]

After replacing \( e_1 \) by \( e_1 - e_0 \) and then interchanging \( e_0 \) and \( e_1 \), the new generators fit exactly into the dual format:

\[
\begin{pmatrix}
  e_1 & e_2 & e_3 \\
  \ & e_4 & e_5 \\
  e_0 & \times & \times \\
\end{pmatrix}
\]

\[
\begin{pmatrix}
  \ & \ & \ \\
  \ & \ & \ \\
  \ & \ & \ \\
\end{pmatrix}
\]
Remark

The action of the cyclic group $\Gamma_{n,q}$ on $\mathbb{C} \times \mathbb{C}$ can uniquely be extended, as we have seen, to an action on the trivial bundle $\mathbb{P}_1 \times \mathbb{C}$ over $\mathbb{P}_1$. The quotient $X_{n,q}$ possesses a holomorphic mapping $\psi : X_{n,q} \to \mathbb{P}_1$ with a singularity of type $A_{n,q}$ over the origin 0 resp. of type $A_{n,n-q}$ over $\infty$.

Conjecture

The Artin deformation of $\psi^{-1}(\mathbb{P}_1 \setminus \{\infty\})$ can at $\infty$ be extended to the Artin deformation of $\psi^{-1}(\mathbb{P}_1 \setminus \{0\})$. 
Dès que nous exprimons quelque chose, nous le diminuons étrangement. Nous croyons avoir plongé jusqu’au fond des abîmes et quand nous remontons à la surface, la goutte d’eau qui scintille au bout de nos doigts pâles ne ressemble plus à la mer d’où elle sort. Nous croyons avoir découvert une grotte aux trésors merveilleux; et quand nous revenons au jour, nous n’avons emporté que des pierreries fausses et des morceaux de verre; et cependant le trésor brille invariablement dans les ténèbres.

(Maurice Maeterlinck, *La Morale Mystique*, in: *Le trésor des humbles*)
How strangely do we diminish a thing as soon as we try to express it in words! We believe we have dived down to the most unfathomable depths, and when we reappear on the surface, the drop of water that glistens on our trembling finger-tips no longer resembles the sea from which it came. We believe we have discovered a grotto that is stored with bewildering treasure; we come back to the light of day, and the gems we have brought are false – mere pieces of glass – and yet does the treasure shine on, unceasingly, in the darkness!

(*Mystic Morality*, in: *The Treasure of the Humble*)
(Translation by Alfred Sutro)
Final Motto

Toric duality between $A_{n,q}$ and $A_{n,n-q}$
